RECENT IRON AND STEEL PHOUSTRY IN COMPUBLIST CHIEFA

Communist China started its third 5 year plan for the iron and steel industry after undergoing an adjustment poried minor 1961. The entire iron and steel industry in China has made advance in productivity, quality and types of products. The Peiping MCMA of 15 June reported that steel, steel materials and pig irons produced during January through May of 1966 far surpass these produced during the same period last year. The production of iron and steel during 1966 has improved each menth and the types of steel materials totalling ever 250 have been successfully test manufactured. Host of the test manufactured materials are of high temperature resisting, high pressure resisting and lew pressure resisting materials. Among them are steel for high pressure receptacles, which can resist several hundred atmospheric pressure, needed for petrolece and chemical industries; high heat resisting materials for manufacture of internal combustion engines and turbines and less head remisting exact date for manufacture of large exygen gas facilities. The production of large quantity of steel materials has made Communist Ohim self sufficient and thus destroyed the blockade of China formed by importalized and reconstruitme.

### Anshan Iron and Steel Company

The quantity and quality of paterials produced by the Anshan from and Steel Company [hereafter referred to as Anshan Steel] have greatly improved and the cost of production has been lawored considerably (NCMA 29 June 66). It is said that the amount of funds of funds to the state by

the Anshan Steel during the entire year of 1965 is equivalent to the amount required to build ninety chemical fortilizer plants of 100,000 ten capacity (per annum) (NCNA 28 April), but the amount of materials produced during the first five months of 1966 is enough to build 50,000 "Chich-fang" brand trucks and the funds set aside for the State is equal to the amount needed for the construction of over 40 large size blast furnaces (NCNA 29 June). An average of 1.3 new product was produced each day during 1965 but the average has risen to 2.1 and the amount of new products test produced successfully during 1966 has already doubled from last year..

has gene 8% beyond the plans of the Anshan Steel and the production of steel ingets, cokes, firepreof materials and steel tubes has surpassed the target. An iren ere production is 15% greater for the same period of last year.

Anshan Steel produced ever 5 million tens in 1959 after the basic construction of the company was completed. Steel inget production reached 4 million tens. After the "adjustment period" from 1961 to 1965, improvement in facilities was made to further improve the production capacity.

During the "adjustment period", which began in 1961, an emphasis was placed on the source of raw materials. A construction of two Ta-ku-shan iron ere mines, an iron ere mine for epen-hearth furnace and a magnesite mine was carried out. By 1963, twelve new mines including these given were established. Some new plants were included among the new construc-

tion which made possible to include products such as short metals.

1. 10 mm (1. 10 mm) (

During 1965, an iron ere crushing plant at Yen-ch'ien-shan iron ere mine, sintering and sifting facilities at Tung-an-shan Sintering Plant, an acid-alkali wash shep and a large exygen station were completed. The completion of these facilities has a great significance. For axample, a mechanised ere crusher is capable of crushing 60 tens of ores in two minutes which improves the production capability. The exygen maker at the exygen station is able to separate exygen from nitrogen by freezing the air at -170° C. In other words, a basic condition required for the open hearth exygen method of steel making has been established at the Anshan Steel.

Furthermore, the Anshan Steel used the most medern techniques in removating the large blast furnaces Ne.4, Ne.7, Ne.9 and Ne. 10 during 1965. Instead of liming the bettem of each blast furnace with fire-bricks, high heat resisting- corresion resisting carbon bricks were used and the sides were fitted with cooling limings. New automatic detectors to detect corresion and burning through have been installed at the bettems of these furnaces. Hot-air furnaces, which have a direct bearing on the production inc wase of blast furnaces and on the consumption of cokes, have also undergone renovation with modern techniques. The results have been great. For axample, the het-air temperature at Ne.9 blast furnace after the renovation has been increased to 1230° C.

Many new techniques and facilities have been introduced at the Anshan Steel. A new relling technique used at the anshan increased

the preduction capacity by 20% (NCNA 10 April 1966). The water cooling methed used in heating furnace, open hearth furnace and blast furnace is being replaced by a vaperization cooling system. It is calculated that if the entire furnaces in Anshan Steel were to be converted to the vaperization system, a saving of 110,000 tens of coal each year, and a reduction of 19 boilers and 10k boilermen can be realized. The steam produced by the vaperization cooling method is used in manufacturing processes and in homes. At the present time, all open hearth furnaces, part of the small and medium size relling furnaces at the Anshan Steel have been converted to the vaporization neithed. ... test on use of this system on blade opening of blast furnace has been generally completed. A conversion to the vaporization system can be done quite reasonably and the results are good. The entire expenses can be recovered in a short time and the life of the cooling facilities can be extended. At the same time, the quality of products has been improved. The Anshan Steel is also conducting tests on the use of hot air blowing instead of a gas in sintering, on production of certain steel alleys, which were fermerly produced only by an electric furnace, through an open hearth furnace, on development of new techniques to consolidate 8 processes used in steel tube casting plant into a single operation and on development of a dry magnetic ore separating plant (NOMA 23April 1966).

### Chungking Iron and St 1 Company

There has been comparatively many news on Changking Iron and Steel

Company (hereafter referred to as the Company), which indicates that the Company produced results worthy of special mentioning. The NCNA of 3 May reported that Company produced 32 new steel products during the first quarter of 1966. The new products include alley structure steel plates and seamless alley steel tubes for petroleum cracking facilities, various het relled steels, superior grade steel materials, special type steel pipes and special steel plates which were net preduced in Cemmunist China. The Company not only succeeded in test manufacture of two new types of alley structure steel plates for KURAMAI [phonetic] oil fields in Sinkiang, but also new materials wital to the manufacture of turbines and also for ceal gas blowing facilities used in metallurgical, chemical and mining industries. The mass production of the new steel materials solved the urgent need for coal gas blowing facilities at 17 industries and enterprises throughout the country. The Company also started on a mass production of stool materials for agricultural use from this year. Those materials include steel plates, die steel and seamless steel tubes for varieus agricultural machineries and equipment. After realizing the value of hexagonal steel lars for excavation of mountains and for drilling in building farms, a positive imprevement in operation was made.

The Company carried out a basic construction on a large scale of propage for production during the "adjustment period." The Congany starts of on 10 projects to be completed by the third quarter of 1965. Inclosed in these projects are: (1) construction of new time cake accordary as which receivery plant, (1) expansion of portion of the construction of the cake accordary as which

fications and types of steel for agricultural use, (3) expansion of seamless tube plant to include production of over twenty types of smaller
tubes, (4) technical improvement of essential facilities for excavation,
ore dressing, crushing and processing at Ch'i-chiang from Mine and (5)
expansion of limestone and dolomite mines. It was also reported that an
8,000 ten annual capacity ammenium sulphate plate and a cruce leadens
plant were completed in Docember of 1963. According to a Chinese newspaper of 9 Nevember 1964, the first phase of the technical reforms in
small and medium size relling plants has been completed at the Company
and the production of steel per hour has been increased by 10%. Furthermore, the mass production and quality imprevement of more complicated
special steel materials (sheet steel, T -steel, I-steel, equare steel,
channel steel), which required difficult manufacturing processes, were

### Shih-ching-shan Iron and Steel Company

Since the "adjustment period", the Shi' ching-shan Iron and Steel Company in Peiping [hereafter referred to as the Company] has been making a steady progress. It is noted that this Company expanded the converter steel making plant using the exygen "upper blowing [literal translation]" steel making process, which has never been used in Communist China up to this time, in early part of 1965. "his exygen plowing method is a new motallurgical technique even internationally. The facilities at the Company were designed, manufactured and installed completely by the Transse

themselves.

During 1958 through 1960, the Company put Ne.3 blast furnace , Ne.3 ceke even and sintering plant into operation. The eld Ne.1 blast furnace of 1920 European type and the Ne.2 blast furnace of eld Japanese type were completely converted and medernized. The No.3 Blast furnace, which was cepied from a fereign type, had a tep charging opening for 20 tens and had to be replaced each year. The charging opening was strongthened in 1963 and is now able to handle over 1 million tens of ores and cekes each year and the eponing which has been used for ever two years is still antact.

The Company eliminated the danger of an explosion and succeeded in centinues blewing of pulverized coal in blast furnace during the year of 1965. The blowing has reached 30% of the total fuel lead of the furnace. It is said that this pulverized coal blewing technique, has not been fully accemplished by ether advanced nations. The success achieved in China indicates the tep technical level China achieved in the metallurgical industry. The Company has achieved injection of pulverized anthracite coal amounting to part of the total fuel used and created combustion with cokes in the inget steel process without causing himirance to the normal operation of the blast furnace and without loss of heat. The Company started the test on this injection technique during the summer of 1963. Thering the test, spentaneous combustion occurred twice and a miner explasion occurred to cause injury to some personnel. Scientists and designers arrived from Shanghai, Hang-chou and Nanking and carried various researCR/CR 332/00016-67 (4 of 5)

# PHOTOS AND PRATURES OF CHINESE INDUSTRY, 15 \*pril 1966 MORRIGHTE RESULES CHAINED HT CHINESE IRON AND STEEL INDUSTRY CHOINARY LOW ALLOT STEEL

China succeeded in refining a world's latest "ordinary lew alley steel", which will be further developed during the third 5 year plan.

This new type of steel refined from eres of various metal paragenesis produced abundantly in China will probably replace the traditional carbon steel, which holds the top position in modern iron and steel industry of the world. Host of the countries still uses carbon steel in most of the machinerises, transportation equipment and construction materials and alley steel is used in small number of products requiring special precision and quality. The world's carbon steel production is around 90% of the entire steel production. China has been fellowing the same pattern; however, the heavier, more breakable, more susceptible to correction and less durable carbon steel does not meet the demand of the Chinese people's economic development. Therefore, they decided to break away from the "western sphere of influence" and started on a great revolution of the Chinese iron and steel industry. The new "ordinary lew willow steel" is the product of this revolution.

# Many Others Being A. 14 Types Feing Re fined and/Test Namufactured

According to the Peiping NCNA of 9 February, China has succeeded in refining the different types of ordinary low alloy steel and tens of new types are being tested. It states that these new steel can be refined in an ordinary tested.

Approved For Release 2003/12/22: CIA-RDP78-04546A003200030007-9

using an erdinary method. The production method is more simple than the method used for special steel. Furthermore, the cost of production is cheaper, the production scale can be large and the usage is as great as the carbon steel, but superior in strength, performance, anti-corresion, warability and longevity. The products made out of ordinary low alley steel outlast products of carbon steel by 30 to 100%. In some cases, this low alley steel can be substituted for nickel-chrome allay steel.

A large use of ordinary lew alley steel in China during the past few years not only revolutionised the steel products but also provided an advantageus condition in revolutionising the other occurring areas. For axample, bridges are now being constructed out of ordinary lew alley steel and are wolded instead of being riveted. The use of this new material cut down the weight and material and simplified the construction work and increased the life expectancy. The use of new steel in a production of high pressure container set capable of producing 50,000 tens of synthetic ammonia a year, cut the weight of each set by 40%, reduce the operating time by about 40% and lower the cost of production proportionately.

Over 100,000,000 tens of freight were transported over rails made of low alley steel but showed little wear and the life expectancy of these rails is estimated to be two to three times longer. A television tower in Canton is 200 meters high and is built out of low alley steel which resulted in the saving of 20% in materials.

In addition, ordinary low allow steel is being used in transportation, machineries, chemistry, petroleum and buildings. It is said that the quality of lecemetives and other relling steeks, eccan going vessels, automobiles, tractors,

procesurised containers, power station facilities and large scale construction materials is very good.

# B. Use of Paragenetic Metal Ores Expands

There is great premise in use of ordinary low alloy steel in China. The MCNA of 9 February 10 A large quantity of various types of metal paragements eres and alloying resources were discovered and are being developed. This will previde an abundant supply for the future large scale development of ordinary low alloy steel."

In regards to various paragonsis erea of Chine, a foreign metallurgist ence said that these are complicated and hard to refine. However, the Chinese iron and steel workers, while studying Hae's Works, understood the phrase "disadvantageous elements" and carried out repeated researches and tests while working and finally evercame the difficulty of refining the paragonesis eres. A read eponed by the Chinese to utilize fully the abundant paragonesis ere resources is highly appraised as bringing about an advantageous condition in premoting "greater, faster and more splendid" development of iron and steel industry of China, in establishing China's can series of iron and steel products and in increasing or even surpassing the world standard in types and quality of steel products.

# C. Over 170 Steel Materials at Anshan Steel tompany

Anshan Steel Company, a largest steel mill in China, has shown especially good results in the refining of low alloy steel. During 1965, Anchen Steel

Company designed and produced ever 400 new steel materials. Of these, 170 are strong new materials made out of lew alleys. These new lew alley steel materials are refined by mixing alleying elements, such as silicen, manganese, beren, and rare earth into an ordinary carbon steel. An addition of alleying elements causes change in chemical composition which strengthens ordinary carbon steel into materials of lew and high temperature resisting, wear resisting and shock resisting characteristics and said to have a better welding quality.

A medium plates plant of Anshan Steel Company successfully test manufactured low alley steel plates of 3mm thickness for automebile chassis frames. These will replace the 6mm carbon steel used in chassis of small jeeps. The reduction in weight affects the leading capacity and cut down on the cest. The workers at a large relling mill succeeded in test manufacture of strong low alley channel steel in August [1965] to be used for chassis in "Hung-ch'i" 100 type tractors because frames buil. -ut of carbon steel often twist after a long use and do not have the pulling power. The new alley steel increased the pulling strength by 37%. Steel plates, L-type steel, square steel and channel steel of low alley steel for bridges are being manufactured by a relling mill and a medium size relling mill of the Anshan Steel Company. The use of these new materials cuts down on the construction time and reduce the weight by 19%.

It is said that the number of types of alley obest and low alley steel produced during January to November of 1965 doubled that of 1960 at the Ahshan Steel Company. During the first 5 year plan (1953-1957), the Anshan Steel Company produced only a little amount of alley steel with an open hearth furnace, but the workers responded to the demand of people's economic development, devised

and expanded the use of an epen hearth furnace in the namufacture of alley steel during the past few years. The use of a large epen hearth furnace is much more economical than the electric furnace in the refining of alley steel, but the centrel of heat and calancel composition of alley steel is relatively more difficult in an epen hearth furnace. However, the workers through assistance of engineers from the Institute of Iron and Steel learned new techniques and succeeded after many experiments. They evercame the difficulties, started mass production and centinue to improve the quality.

The Anshan Steel Company also succeeded in test manufacture of pressure hardening equipment, a facility for production of alloy steel plates. A hardening precess used in the preduction of ordinary lew alloy steel plates is to impreve the strength, tenacity, ductility and impact force. In the past, the Anshan Steel Company used wats to harden ordinary lew alloy steel manually, but this method requires great manpower and the quality of the steel paltes cannot be guaranteed. The new pressure hardening machine operated by push buttons automatically bring heated ordinary low alloy steel plates into the machine, applies 100 tens of pressure with ever 1000 horse hoof shaped pressing devices and temper the plates with water sheeting out evenly and suddenly from ever 20,000 apertures. Engineers who designed the machine, are all young men of the Design Department of the A whan Steel Company. Since these non were newly hired and lacked experience, they toured around over ten shops including reliing and repair sheps. A first design of the pressure hard ming muchane was nearly completed after three menths of research and study and finally succeeded after receiving cooperation of the concerned specialists and after repeated tests and

PH OTOS AND FEATURES OF CHIMESE INDUSTRI, TO. 59, I Jan 60

1965 RESULTS OF COMMUNIST CHIMA'S STEEL INDUSTRY

### A. 500 New Products Successfully Test Manufactured

Communist China attained great results in steel industry during 1965.

According to Peiping MCNA despatch, Communist China achieved their production goal for steel, pig iron, steel materials, cokes and iron ores one month ahead of schedule, also succeeded in test manufacture of over 500 new steel products needed by the country.

Communist China's goal is to become self sufficient in steel products soon; therefore, they have been carrying out test manufacture of steel products. During the past year, they succeeded in manufacture of stainless and other high grade steel alloys having special heat resisting, high pressure resisting, rot resisting and warp resisting characteristics. Some of the steel products of last year include thick plates for high pressure boiler used in 5,000 to 10,000 ton mitrogen fertiliser facilities, light weight channel steel for manufacture of new type tractors, cold relled thick plates, deep drawing use cold relled steel plates, new type propeller shaft steel tube of tough and durable quality for automobile industry, "concave" type spring flat steel, special steel alloy thick plates for petroleum cracking facilities, thin steel tubes, steel pipes for bering oil well beyond 3,000 meters, spiral type oil radiator, and extra low earben stainless steel for vinylon manufacturing facilities. The increase in pig iron production greatly isproved the ratio of self sufficiency in steel age materials which improved the condition for the realization of their third 5 year plan starting in 1966.

The workers of steel industry improved the quality of their products and in the case of an or we hearth steel, the quality is all limit class and the second class was eliminated.

They have also achieved great results in the adoption and development of upward new techniques. The NCMA of 22 December stated that"the advanced oxygen injecting technique in convertors and various injecting techniques in blast furnaces are now being applied in production. The sheet rolling mill lifts of Shanghai No. 3 Steel Plant are being widely propagated through other rolling mills in China. The coal blended cake technique developed in China is being adopted in various coke plants. These new techniques formed a technical foundation for faster and better development in iron and steel industries of China."

### B. Over 400 New Products at Anshan Steel Company

The Anshan Steel Company, a largest steel plant in China, designed and produced over 600 new steel materials used for agricultural machines, petroleum and chemical industries, automobile industry, light industry and for newly rising industries. In addition, high strength steel tube for oil drilling, steel plates for high pressure centainer of 300 atmospheric pressure, seamless tube of less thick, sure plates for 10,000 ton ocean going vessels, and materials for tractors and automobiles. The company also produces in large quantity steel of various sizes and chapes.

Most significant achievement of this company was the success in tent manufacture of over 170 types of low alloy high strength steel. This type of steel is highly regarded by all advanced nations. In the manufacture of chis steel,

a small amount of alleging element such as silicon, manganess, boron and rare earth are added into an ordinary carbon steel. The chamical reaction caused by adding these elements strengthans the ordinary carbon steel to withstand lex and high temperature, wear and shock and improves the welding characteristics. The cost of manufacturing is reduced because of the small quantity of alleging element used. It has been estimated that the cost of commedities and facilities can be reduced by about 20%.

Communist China has been using 6mm ordinary carbon steel plates in chassis and frames of small mise jeeps, but has been changed to 3mm plates developed by the Anshan Steel Company. The reduction on thickness there exists had incorparity, decreases the weight of vehicles and also the cost of production.

It is said that the use of low alley high strength channel steel manufactured successfully by the Anshan Steel in August 1965 in chassis and frames of tractors increases the pulling power by 37%. It was discovered that the twisting of chassis and frames of "Hung-ch'i" tractors after long use was due to inadequate strength of steel used; therefore, the workers of the plant came up with this ew steel material.

The steel plate and rolling mill and the medium size relling mill of the Anshan Steel Company are manufacturing levialloy high strength steel plates, I steel, excise steel and channel steel for bridges. It is claimed that the weight of bridges has been reduced by 19%.

The projection of this low alloy high strength steel is small in relation to preduction of other steel materials but the workers at Anshan Steel will continue their efforts conducting researches, increase commodities and excend

production for the people's economic development.

# C. Improvement of Basis Structures and Blast Furnace at Arthan Steel

Another reticable accomplishment of the Anshan Steel Company is the completion of plants for course crushing of iron orec, sintering, sifting, rolling, "acid-alkali bath" and large oxygen station. These plants are now in production.

The iron ere crushing plant is located at Yen-chien Shan iron ore mine.

Prior to the construction of this plant, workers used to crush ores with [sledge] hammers, but the plant is capable of crushing 60 tons of ores in two minutes which will increase the production many folds

Sintering and sifting plant was completed at East Anshan Sintering Plant which indicates that better quality material will be fed into the production of steel materials.

The newly constructed acid-alkali bath will remove rusts and other blemishes from the surface of steel materials to improve the quality of steel products.

A large exygen manufacturing machine installed at exygen station converts liquified air to below 170° and later resolve exygen and nitrogen. This station was established to promote development of open hearth exygen steel making techniques.

Designing and manufacturing of forfillties for above plants were all couring out domestically by the Chinese works as

In addition to above, the Arabau steel Sommany has no labed on the blast furnaces No.4, No. 7, No.9 and No. 10 under the cost modern

Out of the four renovated furnaces, No. 10 was built by the Chinese but the ether three were left behind by the Japanese and was considered not able to comply with the demands of technical development. However, renovation combined with everheuling was carried out last year. The bettoms of blast furnaces are lined with high temperature resisting and anti-erosion carbon bricks instead of fire-proof bricks and the entire sides have been lined with cooling liners. The bottoms are equipped with most modern automatic checking devices which detect erosion by water at the bottom to insure safe production. It is said that the renovation.

A hot blast furnace, when has a direct relations in production increase and in decrease of cold construction of the blast furnaces, had been renovated to utilize modern techniques. The No. 9 furnace is now able to produce 1230° C compared to around 1000° C prior to renovation. It is said that such high temperature is rarely seen in steel industry of the world. The increase in blast temperature results in saving of about hoke of cokes for every ton of ores refined and the production has increased by 8%.

All fire resisting materials, electrical and mechanical equipment used in the renewation of blast furnaces were made domestically by the Chinese. Engineers of Chingking and Anshan Ferrous Metallurgical Designing Academies, who carried out the renovation work, not only acquired modern technical expuriences but succeeded in introducing technical reforms to many blast furnace workers of China.

# D. Chungking Steel Company Produced 42 New Steel droducts

The Chungking Steel Company also produced creat results during 1905.

TO A STANDARD SEE AND THE AND THE NUMBER OF COMMENTS

The empany succeeded in producing 12 new steel products including composite stainless steel places used in manufacture of facilities for chemical and petroleum industries. Small channel steel, I steel, medium concave type flat steel for manufacture of parts for agricultural equipment, such as tractors and combines, and props for mines are also being produced.

The composite stainless manufactured successfully have the anti-corrosion characteristics of the alley steel and the merits of the carbon steel. The Manufacture of composite stainless not only economize the use of nickel and chrome but cost much less than the ordinary stoinless steel plates. Technical aspects and rolling techniques used in the manufacture of curved steel material for mines were very difficult, but the designers worked together with the plant workers and evercame the difficulties. The company succeeded in rolling 12 new products within the one year period and these new products will go into mass production from 1966.

In addition, the Changking Steel Company maintains a top resition in the production of steel plates for ship building and believe. St el plates from this plan are shipped directly to "several tens" believe plants and shop participating the past year (1965), the acceptance rate of plates for believe acceptance to 99.8% and the plates for ships rose to 99.86%, which shows as improvement of 0.16% and .11% respectively over the rate at the beginning of the year.

### E. Special Results Obtained by Metallurgical Schoolings in Metallurgical Schoolings in Metallurgical

The metallurgical industry in Peiping produce a management of the metallurgy, rare earth nodular graphite cast iron products and orceions and

wires for instruments and guages.

Peiping area is making a repid development in powder metallurgy. Over 300 new poducts are produced. These include iron, copper, molybderum, tungsten and nickel powders pressed into various bearing metals, machine parts, filters, electronic and refrigeration elements and into hard metals, such as diamond metallurgical tools, ferrite materials and "hard to melt" metals. These products are being widely used in automobiles, tractors, textile machineries, agricultural equipment and Leasuring instruments. The oil-less tearing metal of iron powder metallurgy produced last your by the Peiping T'ien-ch'iao Powier Metallugical Plant is now being use, in manufacture of close to 100 types and specifications. Over 900,000 pieces have been produced. The production of this type alone saved 250 tone of bronze last year (presumably by the plant). In the past, parts for scrapers and pumps manufactured by Peiping No.1 General Use Machines Plant were first cast the bronze and machined but has changed to powder metallurgy. The quality of the compressed copper powder meets the specifications and the first production of 30,000 parts has already saved 10.8 tens of 'renze, 33,000 man hours and about 25 milling machines.

The nodular graphite cast iron produced in Peiping is known for its long life. This type cast iron produced by adding rare earth elements is used for roller at relling mills, bearing metals for locomotives, crank axles for automobiles and parts for machineries used in agriculture, textile, chemical industry and medical equipment.

A rare earth high sil on heat resisting grinder studied and test numufactured jointly by the repair and assembly plant of the Peiping Electric Train

Company and the Ch'ing-hua University showed no signs of wear or scrutches even after using it for ever 50 times. A heat resisting grinder of high carbon steel would require a replacement after 20 uses. The cast iron relier processed with rere earth elements by the Peiping Roller Plant has three times the life of a relier of magnesium cast iron rell and twice the life of a cast steel roll.

The state of the s

A spheroidizing agent is used in the manufacture of nodular graphite cast iron, but the use of magnesium created high rate of rejects because the cast materials from this type of cast iron often had defects of some sert. Furthermore, magnesium powder put into a boiling water causes a violent heat radiation and a cloud of dust and smoke which can be detrimental to workers' health.

However, the use of rare earth elements (commonly known for 15 lanthanium types given in periodic table of Mandelev [phonetic] element and yttrium and scandium) as spheroidizing agent removed most of the above problems.

The Peiping Steel Thread Plant succeeded in producing electric resistance parts of iron, chrome and aluminum for remote control and remote measuring.

The product is almost invisible to the naked eyes but possess a high electric resistance rate and is very sensitive. This is also used in measuring devices, medical facilities and communication devices. Not too many countries are able to produce such a fine product.

The Peiping Steel Thread Plant is made up of former 16 rope factories started to contribute toward meeting the demand of the nation in 1958 and succeeded in the manufacture of imprehense-aluminum product in 1961. The plant test acquires and 112 items during 1965.

Part II, No. 50

0:10 332/A 1112 m

Recent Technical Reforms in Communist China's Iron and Steel Industry

Communist China's iron and steel industry is again attaining steady results this year. Iron and steel production figures have not been announced since 1961 and they were not announced this year but, according to a NCNA cable from Peking dated 23 July, over 280 varieties of new steel materials were successfully trial manufactured by the various iroa and steel enterprises during the first half of this year (January through the end of June). The Chicom iron and steel industry his been exerting its utmost efforts in recent years on olversification and the trial manufacturing of new iron and steel products. Accordingly, her self-sufficiency rate in steel materials is rising steadily. The steel materials successfully trial manufactured this year included over 30 varieties of special persons ace steel materials needed for chemical fiber manufacturing plants; cold strip steel sheets, wide cold-strip steel sheets and common shart steel fale needed for manufacturing new model automobiles and an event, oil pipe needed to dig over 3,000-meter deep oil wells; i20 mm chick high pressure steel plates needed for large nitrogenous. I stillize equipment and large power generation equipment; and steel materials requiring complex and advanced techniques. These steel man rises to ornation Communist China's self-sufficiency rate a step higher than its force self-sufficiency rate of 95 percent.

The An-shan Iron and Steel Corporation, which is the larged iron steel enterprise in Communist China, exceeded its production of its steel materials, steel ingots and pig iron for discretely on the exceeded its production of its calculating in terms of average production standed to the exceeding increases for this corporation compared to its production desired for the 4th quarter of last year was 8.8% in steel materials, 9.6% is attached and 16.2% in pig iron.

The above results cannot be separated from the recent tables, relearns being rigorously advanced in Communist China's iron and sceed industry. These technical reforms are not limited to the iron and steed industry. Taking the form of a mass movement, they are being appointed or some scale in various areas of production including, which have any areas entry to compare, learn, overtake and support. During the most sixty to example, the workers of the An-shan Iron and Steed Conjunction and it over 10,000 technical reforms and technical reversation proprocess and of them were implemented. The Wuhan Iron and Steed Conjunction with a second largest iron and steed combine in Communist China, the state of implemented over 250 reforms to increase the daily production of its infurnaces 5-10 percent and to more than deable the life agency and copen-hearth furnaces. These technical reforms a second by the implementation of the other iron and steel constraints in force of the production in Communist China are as follows:

# Shorties of Puel Injection by the Plast Purnaces of the An-shan Iron

According to a NCMA An-shan cable dated 18 July. he various blast furnaces of the An-shan Iron and Steel Corporation have been employing a law fuel injection rechnique since April of this year. Coke is the principal fiel being used by the blast furnaces for smelting pig iron. Since the ligitation of liquid or gaseous fuel would result in huge savings of coke inderested in capacity of the blast furnaces, the nations throughout the world possessing highly developed iron and steel industries are extremely interested in this new technique. Various types of fuel can be injected into the blast furnaces i.e., heavy oil, natural gas, coal dust or a mixture of coal dust and heavy oil; the fuels being used by the An-shan Iron and Steel Corporation are heavy oil and tar oil.

In 1963, the Am-shan Iron and Steel Corporation began testing and experimenting with the new techniques in fuel injection. It began injecting heavy oil in Blast Furnace No. 1, trial injecting tar oil in Blast Furnace No. 2 soon thereafter, and succeeded in both attempts. On the basis of these experiences, the Am-shan Iron and Steel Corporation mobilized its workers and dispatched them to neighboring iron and steel enterprises to propagate the use of fuel injection in blast furnaces.

The adoption of fuel injection has resulted in a huge decrease in the consumption of ceke at the An-shan Iron and Steel Corporation. According to calculations, of the various factors contributing to the decrease in the consumption of coke, fuel injection accounts for about 40 percent. The decrease in the consumption of coke reportedly saves 170,000 tons of coke per year and lowers operating costs more than 4,000,000 yuan (about 600,000,000 yen). Since the sulphur content of heavy oil and tar oil is less than the sulphur content of coke, the sulphur content of the pig iron is reduced substantially, resulting in an overall improvement in the quality of the steel. Fuel injection is also extremely profitable because it equalizes the temperature within the blast furnace, improves the technical conditions for the operation of the blast furnace, prolongs the life expectancy of the furnaces, produces good quality products and guarantees security.

## Installation of a Simple Steam Collection Device at the An-shan Iron and Steel Corporation

In Pabrus of this year, a simple steam collection device was installed on one of the bloom heating furnces of the medium-size rolling mill of the An-shan Iron and Steel Corporation. This device is capable of collecting four tons of steam per hour. This steam attains a pressure of 3.5 times atmospheric pressure, which is sufficient to satisfy all the needs of the mill including the coal gas producer, the steel material acid tank, the mess hall and room heating.

The thermal energy dissipated monthly by the 7-unit cooling water pipes of the two bloom heating furnaces of the medium-size rolling mill of

the An-shan Iron and Steel Corporation is equivalent to the thermal capacity generated by over 1,000 tons of coal. Noting the steam being dissipated from the cooling water flowing out from the bloom heating furnaces, the workers began giving thought to a method for collecting and utilizing this untapped source of energy. After a series of experiments by the workers, technicians and order of this medium-size rolling mill, they successfully drafted a blueprint for this simple steam collection device during the first quarter of last year. They were aided in this technical reform by funds and technicians provided by the loaders of the An-shan Iron and Steel Corporation. Finally, in February of this year, after a 5-month effort, this steam collection device was installed on one of the bloom heating furnaces.

The technique of collecting the steam from the cooling system of the bloom heating furnace, which is commonly referred to as "vapor cooling", is a new technique that began appearing throughout the world this past ten-odd years ago. A number of industrially developed countries are extremely interested in this technique becasue it permits the collection and use of this huge volume of wasted steam for production and livelihood neds; it also curtails the need for special steam generation equipment and manpower. The successful adaptation of "vapor cooling" by the nedical size rolling mill of the An-shan lead of the dependent of being noted with interest becasue it heralds the adoption of this mean technique by Communist China.

According to the officers and cadre of this medium size colling mill, the merits of steam collection are as follows:

- 1. Huge savings in auxiliary equipment and maintenance costs. By collecting steam from the bloom heating furnace, this rolling mill has been able to suspend the operation of its two steam generation boilers; preparations are under way to divert them elsewhere. By adopting vapor cooling for the other bloom heating furnace, this rolling mill be able to eliminate its entire cooling water heat radiation equipment—water tower, reservoir, pump and cold water stand. Thus, in the construction of rolling mills hereafter, invaluable experience has been sained whereby there will be little or no need to construct steam boilers and no need to construct cooling water heat radiation equipment.
- 2. Savings in manpower, water, coal and electric power. After implementary vapor cooling, this rolling mill realized savings consisting of 15 workers, and over 800,000 tons of water and 5,000 tons of high-graphs coal per year.
- 3. Steam collection is beneficial for extending the life of the equipment for cooling bloom heating furnaces and for raising the quality of steal materials.

Moreover, from the experiences of this medium size rolling mill, th.

Contact to the beautiful to the second of the second

technical aspects of this vapor cooling equipment is not very complicated, it does not require a large investment, its construction period is short, it does not require special materials and its total investments can be recovered in an extremely short period. This medium size rolling mill recovered its total investments of 33,000 yuan (about 5,000,000 yen) in merely two months and is beginning to show a profit of 25,000 yuan (3,750,000 yen) per month.

The medium-size steel sheet plant, the small-size rolling mill, the pipe welding plant, etc. of the An-shan Iron and Steel Corporation are actively engaged in the implementation of this new technique. Some are designing fixtures and some are already in operation.

An-shan Iron and Steel Corporation's Resintered Ore Measuring Instrument and Hydraulic Spinner for Dressing Ore

Extremely noteworthy are the An-shan Iron and Steel Corporation's two major innovations to raise the quality of sintered ore and dressed ore.

The innovation for raising the quality of sintered ore, called the "resintered ore measuring instrument", is a measuring instrument which was successfully manufactured by YANG Kuei-hua, senior gas engineer of Sintering Shop No. 2 of the General Sintering Plant of the An-shan Iron and Stuel Corporation.

In the process of producing sintered ore, small granules of ore are produced which must be sintered again before they are usable. They are called "resintered ore" in Communist China. Heretofore, the General Sintering Plant of the An-shan Iron and Steel Corporation did not possess the equipment for measuring resintered ore. Accordingly, the quality of the sintered ore was affected because they could not gage accurately the amount of ore to be resintered. The ideal method for resolving this problem was to equip the plant with a resintered ore measuring instrument but Communist China had never manufactured equipment of this nature before and the Chicom technicians had checked through foreign technical data but they were unable to find an appropriate method. Making up his mind to construct an appropriate instrument through his own efforts, and obtaining hints from round HIMICHI (phonetic) calculators, etc., YANG conducted a series of experiments and, finally, after six experiments supported by the party organization, plant cadre and plant workers, he succeeded in trial manufacturing this resintered ore measuring instrument.

Resintered ore measuring instruments are attached to four sintering machines of Sintering Shop No. 2 of the General Sintering Plant of the An-shan Iron and Steel Corporation at the present time. Fifteen menths of actual production verify the fact that these measuring instruments have stabilized and raised the quality of sintered one to a mark of degree. The quality of Sintering Shop No. 2's sintered are was raised from about 95% acceptable to over 99% acceptable during the past several year, and.

in April and May of this year, it attained the ant-time high of 160 acceptable.

The quality of the An-shan Iron and Steel Corporations's ore stressing was raised appreciable due to the introduction of the hydraulic spirals .

The machinery being commonly used for dressing are in Demmarkst Grins at the present time is the spiral separator. The crashed are is passed through the separator and the finely ground are grantles are in letter for smeltering. But this machinery weighs as much as 46 tens, its structs is huge and bulky, and it is relatively inefficient.

The hydraulic spinner, a type of centrifugal separator, had been used heretofore by Chicom iron one and coal dressing plants exclusively as a water and dirt remover but, internationally, it had been attaining favorable results as an one dressing separator. With the support of related selectific research units, the An-sha Iron and Steel Corporation had been conducting years of experimenation and research on the use of the hydraulic spinner as it will be supported to the required techniques.

By replacing the spiral separator with the hydraulic spinner, the An-shan Iron and Steel Corporation has been able to improve the granular size of its ore dressing and to raise its separation efficiency about 9%. This hydraulic spinner weighs merely one ton, its structure is simplered one hydraulic spinner represents a saving of 80,000 kWH of electric power per year. Moreover, this vital innovation is available to all the operational dressing plants throughout Communist China.

According to an article by HO Cheng-p'ing in the Jensmin Jih-pac dated 16 August, the East An-shan Steel Mill has improved it bematite flotation process and made a hugh contribution to greater production by lowering its daily losses in refined ore granules from over 150 tens to about 8 tons. Moreover, it has contributed greatly to the developmental hematite floration techniques in Communist China.

Whether the hydraulic spinner method is or is not being employed a unknown.

Overall Life of Open-Hearth Furnace No. 20 of the Am-shan from and  $S \in e^{\pm}$  Corporation

The large Open-Hearth Furnace No. 20 (charge increased from 360 team to 440 tens in April 1959) of Steel Mill No. 3 of the An-shan Iron and Steel Corporation has been operating its throat, front and rear wells and mouth continuously for 20 months to set an overall furnace-life record totaling 1,210 runs. This may also be called a major technical innovation.

A STATE OF THE PARTY OF THE PAR

The state of the s

Overall furnace life must include, in addition to the throat of the epim-hearth furnace, its front and rear walls, its mouth, its sediment reem and its regeneration room. From 9 September 1963, when Open-Hearth Ro. 20 was pertially repaired and returned to service, through 8 May of this year, its technical and economic indices - fire-proof material, fuel consumption, coefficient of utilization, rate of operation, smelting time, etc. - have attained the top level among the similar type open-hearth furnaces in Communist China. For example, its coefficient of utilization (tons of steel manufactured in 24 hours per 1 m<sup>2</sup> furnace floor) rose to (tons of steel manufactured in 24 hours per 1 m<sup>2</sup> furnace floor) rose to 9.26 tons, 1.29 tons higher than the previous period. It consumed 7.07 Kg of magnesium fire-proofing material per ton of manufactured steel, which is the lowest record in the consumption of magnesium fire-proofing material is the lowest record in the consumption of magnesium fire-proofing material is the lowest record in the consumption of magnesium fire-proofing material is the lowest record in the consumption of magnesium fire-proofing material is the lowest record in the consumption of magnesium fire-proofing material is the lowest record in the consumption of magnesium fire-proofing material is the lowest record in the consumption of magnesium fire-proofing material is the lowest record in the consumption of magnesium fire-proofing material is the lowest record in the consumption of magnesium fire-proofing material per ton of peration rose to 92.74, which is 2.95% higher than the previous period. Thus, during this period, which open-hearth furnace exceeded its production goal by ever 35,100 tons of quality steel.

In length of continuous service and number of smelting runs, the record of this open-hearth furnace and its various components is unprecedented in the history of steel manufacturing in Communist China and unique in the history of steel manufacturing throughout the world. In the future development of the overall life of Chicom furnaces and their components, the experiences gained from Open-Hearth Furnace No. 20 are expected to be invaluable. For this reason, many of the workers from other open-hearth furnaces are being dispatched to Open-Hearth Furnace No. 20 to study its advanced techniques.

# Shin-ching-shan's Oxygen Blow-Up Steel Manufacturing Method, Etc.

Another advanced and noteworthy steel manufacturing method is being employed at the newly added revolving furnace steel manufacturing plant of the Shih-ching-shan Iron and Steel Corporation. It is a new metallurgical technique called the revolving furnace oxygen blow-up steel manufacturing method. All the machinery for this plant was designed, manufactured and installed by Communist China herself. The construction of this plant represents new development in Communist China's metallurgical industry. It can be said that she has gained the experience to construct additional new and larger plants.

The successful trial-manufacture of a new surface cutter for smoothening out the surface irregularities on steel materials and castings by the Shen-yang Wireless Equipment and Materials Plant has made a noteworthy contribution to Communist China's steel materials processing techniques. Heretofore, Communist China had been removing the surface irregularities on her steel materials and castings with his chisels and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low efficient and electric grinders, resulting in excessive waste, low electric grinders, resulting in exc

effort, it is 20-odd times more efficient and it improves the quality of the finished product. This new surface cutter is being used on a trial basis in a number of plants affiliated with the An-shan Iron and Steel Corporation with favorable results.

The above represent the key technical innovations reportedly adopted by the Chicom iron and steel industry during this year. In conclusion, special mention must be made regarding the hugh efforts being employed and the major results being attained in the utilization of industrial waste by the three major industrial cities in Northeast China - An-shan, Fu-shun and Shen-yang. How to utilize, dispose of and convert industrial waste to profit is one of the major problems confronting industrial production and city construction. An-shan, Fu-shun and Shen-yang were typical of the initial Chicom cities to experience this problem. From last year, they began implementing as many as 205 major and minor projects dealing with the disposition and utilization of industrial waste including the construction of city sewage treatment facilities, city sewage water trunk lines for farm irrigation, drainage for possited water from plants and mines; settling reservoirs, neutralizing reservoirs, recovery towers and dust removers for waste gases; brick and cement plants using waste matter as raw materials; and other recovery equipment. 83 of these projects have been completed in successive intervals and they are already in operation. In Shop No. 2 of the General Sintering Plant of the An-shan Iron and Steel Corporation, for example, close to 100 tons of fine ore is being recovered from soot daily.

CHIMA'S NEW NIXED COAL THEORY WHICH HAS MORE THAN DOUBLED COAL RESCURCES AS RAW MATERIAL FOR COKE

STAT

So-called coke which can be obtained with high-temperature carbonisation of coal is for the most part used in the metallurgical industry. Especially, a great amount of coke is consumed in iron manufacture, and coke used for iron manufacture must have especially excellent quality and good quality raw materials are necessary. However, raw material coal of good quality is not produced everywhere, and recently there has been caution concerning its world-wide insufficiency. Even in China, coal deposits are abundant, but comparatively little coke coal has been prospected until now. Moreover, accompanying the rapid development of the metallurgical industry, demand for coke has daily increased, producing a stringency of raw material coal. However, in China the former rixed coal theory has been recently broken through, and various kinds of coal which until now have been considered to be unusable in cohe carbonization have appeared on the scene and opened up a great future for the metallication industry and the coke industry.

Paction Iron and Steel Company Weigh Firstly Weed Looks Foel

The Paot'ou Iron and Steel Company was built in 1957, and since beginning operation, it has hardly been able to use the abundant coal of Inner Mongolia for coke carbonization, its percentage being less than 10 percent and at times not exceeding a percent. Depending on the extent of change of quality in coal formation, there is coal from the very worst peat and brown coal to long-burning coal, gas coal, rich coal (hitan), coke coal, lean coal (rotan), poor coal, and anthracite coal. Among these, as raw material coal for coke are used

the four kinds of gas coal, rich coal, coke coal, and less coal.

Gas coal is a kind of bituminous coal and contains comparatively much volatile matter, and when air is cut off and it is heated, a large amount of coal gas and chemical products are formed. However, since gas coal, at the time of carbonivation, gives off a grant sould for a coarse coal, at the time of carbonivation, gives off a grant sould for ince gas coal, at the time of carbonivation, gives off a grant sould for ince gas and contracts, very many stender lan invidinal cracks the formal duced, and since the coke breaks easily, it is very unfavorable for its voletile matter is lower than gas coal, as find an ince when it in its voletile matter is lower than gas coal, and the coal ince white the coal is a inferior, and it is stall one nested easily, this is also not ideal coke for use in sactions. Considerable casily, this is also not ideal coke for use in sactions. The voletile matter of lear coal is very little and the colloied budy is sound trackly little, and lumps of the carbonized coke on large and the voletile matter of lear coal is very little and the colloied budy is sound trackly poor, and consequently, it cannot be used independently in the company facture. Only cake coal is an ideal raw matterial coal which which when a stender produces colloidal body of mood heat resistance, has high carrier at the produces colloidal body of mood heat resistance, has high carrier at the contains and antiabrasive property are good. However, recourse of it are not very great, and moreover, since it has great expended on pressure, as an it is placed independently in coke ovens, it constinct descriptions. Consequently, coke is made by combined a thought of coel at a suitable ratio.

In the experience of foreign countries, it has been non-ic red up to now that coke coal has to be principally used in mixed coal, with at least 30 percent, and that a fixed ratio of rich coal, has coal, and lean coal, cannot be freely changed, and this manner of thinking was taken over in China. And, in Inner Mongolia there has been such gas coal and rich coal, with very little coke coal and even less lean coal.

Since most raw material coal has been cought long distances from Shansi, Hopeh, and the Northeast, the source of supply has been unstable, the quality low, and the recovery rate of chemical prod ats bed and cost high. Therefore, the Metallurgical Industry Department and the leadership of the Pacticu Iron and Steel Company had formerly proposed to the coke plant establishment of coal supply sources in Inner Mongolia. However, some of the administration, leadership, and technicians of the soke plant were under the restraint of foreign experience and theory, and having had a fixed concept for a long time concerning Inner Mongolian spal, did not lend an ear to this opinion. Some of the technician of the coke plant had a different opinion concerning this question, but did not succeed in shaking the forces

Decision to the Mississis Book in the Anti-Waste Movement

Is the series of production, economy movement

distant transportation of coal is counter to the fundital principle of vational utilization of national resources and mic. The a ed-coal rule of foreign countries asserts that is not principally combined in coke coal, good quality cebe caused be made. This rule was largely produced and formulated in countries of abundant coke coal resources and is suited to their ditions, and by means of it, coke of good quality and low price is manufactured. However, in countries of not vary abundant coke coal resources, the coat becomes high, the production amount is limited, and without fully utilizing China's coal resources, development of China's iron and steel industry is hindered. In China, based on the status of China's coal resources situation, there had to be a mixed-scal rule which corresponded to the characteristics of resources of various places. However, for this, revolution was necessary, and first of all the old restriction of foreign theory had to be broken through. The leadership and technicians of the coke lart became enlightened through studying philosophy, and breaking through the restrictions of foreign theory and setting out from the actual situation in China, they strengthened their resolve to seek out a new path for solving the problem of coal used for coke by means of research and scientific experimentation.

Breaking Through Existing Theory and Increasing the Percentage of Rich Coal and Gas Coal

In the latter part of 1963, technicians, production management, and supply purchasing personnel of the Paction Iron and Steel Company and the Anshan Coke and Refractory Materials Design and Research Institute investigated in detail several coal mines of the Inner Mongolian Autonomous Region, such as the Shihkuaitzu, Laoshiitan, Niaota, and Yangkoleng coal mines. When they returned, they immediately began research, determining properties of the various kinds of samples and obtaining various data, for example, strength and entiabrasive property, thickness of the colloidal layer, expansion pressure, and They also conducted carbonization experiments in wolatile matter. They also conducted carbonization experiments in semiindustrial control and industrial coke ovens. As a result of the experiments it was round that the industrial cost in the language of the language cost in the language co such things as thickness of the colloidal layer and strength of single-type coal carbonization were all near Chinghoing coal, and single-type coal carbonization were all hear straight over a large system all sokin that it is good quality coal. However, the straight over the property, structural strength, and antiacrosive projecty Inner hongolian Wutangkou gas coal were all inferior to the familian coal which they had used until them. To the try good quality cole be hade substituting these coals? They come to graph with the difficult to gripp with this difficult problem. According to the until them collected, old, observed option, votargeon coal, Chinghaing coal, and the coal of the coal not is interchanged. "owever, they me longer them it we these differences merely characteristics of variety since and see there not also common sepects: At the recult of commune analysis, they discovered that there would very next comen point in

the three kinds of coal, namely, that the amount of colloidal budy which they produce does not vary very much. The thickness of the colloidal layer of Chinghsing coal is 21 mms, of Tarrohan scal by mms, and of Wutangkou coal 22 mms, and thickness and property of the colloidal layer are principal factors determine the viscouty and coking property of coal. If there is not a great difference in the coking property of coals if there is not a great difference in the thickness of the colloidal layers, why cannot mood quality coke code from more gas coal and less coke coal? Is the receipt of himself the experiments, they proved that the coality of the receipt of himself experiments, they proved that the coality of the receipt of himself and experiments, they proved that the coality of the receipt of himself and coal instead of Chinghsing coke on the receipt of the first occase, with suitably increasing the With the coality of the first occase, which is a definite quality could be companized. The cover, that has combined in quality, recovery of chemical reducts (coke hyproducts) increases. In this way, the existing matricular that cover coal premoval and in combinations of coal used for take was for the first of broken through.

Grasping the Merits of Various kinds of toal not in Inclation but Comprehensively

Without studying characteristics of valious kinds of coal in isolation, they studied interactions when several kinds of coal were classified and combined. For example, the volatile matter of (as coal and rich coal is comparatively high, and with the experience until them, it was considered that in cases in which much rich coal was most, then it was considered that in cases in which much rich coal was most, then gas coal could not be used, and that if that were not so, making of the coke would deteriorate. Under the rectraint of this technical restriction, it was thought that when rich coal produced in Inner Mongolia was used, not much Innerphongolian gas coal could be used. Therefore, although the Shihkuaitzu coal mine is near by, since it produces gas coal of inferior coking property, it was not used very more gas coal of inferior coking property, it was not used very lunch. This time, they specifically analyzed characteristics of the Shihkuaitzu coal and discovered that the thickness of its colloidal body layer is only 12 mms, and that the cohing property is bad and the ash content too high. However, the rich coal deposits of the Nisota coal mine are very large and the thickness of the colloidal body layer is generally more than 30 mm. Therefore, they wondered thether if they combined the Shihkuaitzu coal with a large amount of Nisota coal of good viscosity, mutually supplementing merits and demerits, could not good quality coke be carbonzied? After several tens of experiments, and based on the actual situation, they increased the mixture amount of Nisota coal to 25 percent and made the Shihkuaitzu coal about 15 percent. In accordance with that, coke coal was reduced by 20 percent, and good quality coke could be carbonized and the amount of Shihkuaitzu and Nisota coal used increased to more than twice that used before.

Gaining Lessons from Repeated buccesses and Failures

They had many viciseitudes of fortune until they attained masses. At first, when a group of persons proposed that if weak coking coal produced at faturg were partially used and at the same time more rich seal and gas coal of Inner Mongolia were combined it would be possible to increase the volatile matter of the coal, shorten the transportation distance of the coal, and decrease the cost of coke, the plant management was dubious. However, it was learned that another plant was mixing fature coal, and it developed that if everyone thought it would be extremely beneficial, it would at least be tried, and in the first test, when 5 percent was mixed, coke of very good quality was produced. In the second test, it was made 10 percent, and indeed, coke of good quality was produced. Since, by computation, if a 10 percent combination were continued more than 1,400,000 yuan could be saved per year, and even with 5 percent, more than 700,000 yuan could be saved, the plant leadership was delighted and had self-confidence. However, after two days, since the combination of gas coal from the Shihkusitzu coal mine was increased, the quality of coke declined. Thereupon, the old technical restriction again raised its head, and since the Tatung coal did not change to coke, they shrunk from the difficulty saying that it was at times good and bad, and therefore useless.

Also, when by means of a series of experiments they proved that Laoshihtan coal is an excellent rich coke coal which is an appear as Chinghsing coal, the people were extremely delighted. However, a problem arose in coal washing. That was that the recovery take of washed coal was very low, being only about 30 percent. Therefore so of the plant went to the coal-washing workshop and immediately banded down the decision that Laoshihtan coal is useless coarse coal, and that when three tons of coal are washed, only one ton is obtained, and the cost is too high. However, the memority of the technicians and workers thought that since the cause of the low recovery like of washed coal was not clear, it was too early to come to the decision that it was a failure, and they decided to summerize their experience and gain lessons. This time, as the result of detailed stange which extended over several days, it was a read that there is much crusted powder in Laoshihtan coal, and that when washed with mater in is and to congeal and is at times washed away by the mater, which are not to congeal and is at times washed away by the mater, the headen, and technicians discussed and analyzed it together with the sense, and since the operation was improved, the amount of wind and later adjusted, and the congealing problem modives, the recovery total increased to more than 50 percent, and thus, the evaluation of Looshihan coal was changed from bad quality coal to good quality coal.

Seeking the Mixture Ratio and Joke Oven Competer to

Such things occurred many times. It the end of 1905, by scannof more than 200 experiments on from boxes can large one, the massistiction that if coke coal was not principally used, and ease could not be made, was fundamentally broken to be do, and to the

1964 plan for coal use was made, they decided to fundamentally cease use of Chinghsing coke coal and to use 40 percent Inner Mongolian coal. However, later, since the carbonization time was reduced because of the necessity of increased iron and steel production, the quality of the coke again dropped. Encountering a new difficulty, the old restriction which had previously been broken through again raised its head, and it was regretted that indeed soke conl was letter and that when there was little of it, it aid not go well, and that the ratio of Inner Mongolian coal should not be made high. In order to restore the quality of the coke, they increased the combination ratio of coke coal to 25 percent. However, the quality of the did not improve. Upon analysis and research, it was learned to the principal reason the quality of poke dropped was not that the a ount of soke coal used was decreased but was because the combination retio and the carbonization temperature had not conhortened car coning on time. Then the of raw combination ratio and the congerature of the coke oven were and several tens of tests conducted. the quality of coke again race, even though 40 percent Inner Mongolian coal was used and, as before, only 10 percent coke coal was used.

Amount of Inner Kongolian Coal Used Asaches 70 Percent

The ratio of Inner Fongolian coal has gradually incienced and has now reached 70 percent, and the amount of coke coal used has Correspond to 20 percent. With more than one year of practice, it has been demonstrated that the quality of coke and of the lamer Congolian coal has completely met standards and is spitable for use in clear furnaces. The crush-reaisting strength of coke which has meet concerned people has increased eight kilograms from before, and various qualities detrimental to iron manufacture have been greatly and the recovery rate of byproducts which are used the manufacture of agricultural chemicals and increased. The manufacture of agricultural chemicals and increased. The coke reached the second treatment of the Paction Iron and theel do many for the manufacture of a serious and the cold of the reached to have the serious for the second to coke the serious for the second coal, the average transports for the transport of the portation costs have decreased, coke present increased have greatly lowered.

Sixty Percent Cas Coal Used by tobas Thum has about

 The second secon

the temponised colorinas increased from before, and the anh content is also less than in flavious coke. The Wuhin han and Steel Tomping temponises coke qualified for use in iron manufacture using 60 percent embedded of rather high colloidal body (depth of colloidal layer about 18 mm.). The coke plant of the Anshan Iron and Steel Gorgany ratio uses 18 mm.). The coke plant of the Anshan Iron and Steel Gorgany ratio uses 18 percent gas coal, and the quality is good, in it uitable for large-plant furnaces, and ash content is lower than in previous coldeniated blast furnaces, and ash content is lower than in previous coldeniated blast furnaces, and ash content is lower than in previous coldeniated blast furnaces, and ash content is lower than in previous coldeniated blast furnaces, and ash content is lower than in previous coldeniated blast furnaces, and ash content is lower than in previous coldeniated has very great significance for the development of China's coke and metallurgical industries. According to rough statistics, if soke and metallurgical industries. According to rough statistics, if soke is carbonized with rich coal and gas coal as principal raw materials, coal which can be used in coke carbonization, as calculated with deposits which are presently known, will increase trace over previously. If to thet is added coal which has not been used in some coke carbonization, the raw material resources of China's coke industry again greatly increase.

Overcoming All-Country Irrationality "ith New Combination Methods

China's coke industry has for more than the last ten years been completely based on the coal combination theory of foreign constries. Therefore, it has been considered that using the four kinds of coase coal, rich coal, gas coal, and lean coal in carbonization of social, coke coal must predominate and be made at least more than 30 percents. However, in China, among coke raw material coal which has alreasy four investigated, deposits of gas coal are greatest, and there is comparatively little coke coal. Also, the regional distriction of various kinds of coal is unbalanced. Thus, at many the plants, and there is continuated to take the long way around and have tobe real returnal coal district in the large quantity from other districts, and terourhout the solid, the illogical phenomenon has occurred of transportation strength in the devoted to this and the cost of coke less incommand. The committee devoted to this and the cost of coke less incommand.

Bright Puture in Resources of the little 201 Deal to a first to

Dince cole has come to be ear or and the first document of account coal as principal raw materials, the confidence of the coal from long distances or andly and the first coal plants has chemical, these there are a first coal to be a coal t

permit in the constitution of the constitution

matter ratio of coal and has increased chemical industrial products, and therefore, agricultural and fertilizer production has increased.

At present, in all principal coke plants throughout the country, for example coke plants of the Pact'ou Iron and Steel Company, Shih-chingshan Iron and Steel Company, Chungking Iron and Steel Company, and the Wuhan Iron and Steel Company, have been established coal combination experimentation stations, and they are continuously conducting coke carbonization scientific experiments and creating conditions for further expansion of new kinds of use. This new road which has been opened up in resources of raw material coal road for coke which had become a bottleneck in development of the iron and steel in justrica will probably henceforth be widened more and more.
